Laser-Gum Surgery

Chronic and Painless

One of the most common chronic diseases affecting adults is Periodontal Disease. This is a painless disease that causes loss of attachment (gum and bone) around the teeth, ultimately causing tooth loss.

If a deep cleaning won't fully address or resolve the concerns present, there are several different surgical options to help treat this disease.

Laser therapy is a minimally invasive option. This is an excellent option if you have risk factors that make you high risk for complications associated with traditional periodontal surgical therapy.

Goals for Treatment

The top goal is to prevent or delay tooth loss. In conjunction with surgery, our team will help you develop a plan to address your risk factors, improve your daily oral care routine, and establish a maintenance plan. Often you will continue to see our office for ongoing care in addition to the care with your dentist.

Common Risk Factors

- Smoking
- Diabetes
- Poor Oral Care Habits
- Missing professional cleanings
- Immunosuppression
- Poor nutrition
